INTERNATIONAL BUSINESS MACHINES CORPORATION

EXTENSION OF FATIGUE LIFE FOR C4 SOLDER BALL TO CHIP CONNECTION

Background of the Invention

1. Technical Field

The present invention relates to a method and structure for coupling a semiconductor chip
5 to an organic chip carrier by a solder ball.

2. Related Art

A solder ball that couples a semiconductor chip to an organic chip carrier is subject to
thermally induced strain during thermal cycling. The thermally induced strain inevitably causes
damage to the solder leading to cracking and electrical failure if sufficient cycles occur. Thus, a
10 method and structure is needed for reducing the aforementioned thermally induced strain and
increasing the fatigue life.

Summary of the Invention

The present invention provides an electronic structure, comprising:
a semiconductor substrate having a first electrically conductive pad thereon;
15 an organic substrate having a second electrically conductive pad thereon, wherein a
surface area of the first pad exceeds a surface area of the second pad; and
a solder member electrically coupling the first pad to the second pad.

The present invention provides an electronic structure, comprising:

a semiconductor substrate having a first electrically conductive pad thereon;
an organic substrate having a second electrically conductive pad thereon; and
a solder member electrically coupling the first pad to the second pad, wherein a
distance from a centerline of the solder member to a closest lateral edge of the semiconductor
5 substrate is at least about 0.25 mm.

The present invention provides a method of forming an electronic structure, comprising:
forming a semiconductor substrate having a first electrically conductive pad thereon;
forming an organic substrate having a second electrically conductive pad thereon,
wherein a surface area of the first pad exceeds a surface area of the second pad; and
10 electrically coupling, by use of a solder member, the first pad to the second pad.

The present invention provides a method of forming an electronic structure, comprising:
forming a semiconductor substrate having a first electrically conductive pad thereon;
forming an organic substrate having a second electrically conductive pad thereon; and
electrically coupling, by use of a solder member, the first pad to the second pad, wherein
15 a distance from a centerline of the solder member to a closest lateral edge of the semiconductor
substrate is at least about 0.25 mm.

The present invention reduces thermally induced strain that occurs in a solder ball during
thermal cycling, wherein the solder ball couples a semiconductor chip to an organic chip carrier.

Brief Description of the Drawings

FIG. 1 depicts a front cross-sectional view of a semiconductor chip coupled to an organic chip carrier by a solder ball, in accordance with embodiments of the present invention.

FIG. 2 is a table of thermal cycling fatigue test data for the solder ball of FIG. 1.

5 FIG. 3 is a plot of shear strain on the solder ball of FIG. 1 as a function of distance between the center of the chip and the solder ball centerline.

FIG. 4 is a plot of axial strain on the solder ball of FIG. 1 as a function of distance between the center of the chip and the solder ball centerline.

Detailed Description of the Invention

10 FIG. 1 illustrates a front cross-sectional view of an electronic structure 10, in accordance with embodiments of the present invention. The electronic structure 10 includes a semiconductor substrate 12 coupled to an organic substrate 14 by a solder member 16. The solder member 16 is mechanically and electrically coupled to an electrically conductive pad 20 on the semiconductor substrate 12. The solder member 16 is likewise mechanically and electrically coupled to an 15 electrically conductive pad 22 on the organic substrate 14.

The semiconductor substrate 12 may include, *inter alia*, a semiconductor chip (e.g., a silicon chip or a germanium chip). The semiconductor substrate 12 may have a coefficient of thermal expansion (CTE) of about 3 ppm/°C, wherein ppm stands for parts per million.

The organic substrate 14 includes, *inter alia*, an organic material such as an epoxy, a

polyimide, a polytetrafluoroethylene (PTFE), glass cloth, copper-invar-copper or other reinforcing layers, and combinations thereof. The organic substrate **14** may include, *inter alia*, an organic chip carrier. The organic substrate **14** has a CTE between about 10 ppm/ $^{\circ}$ C and about 18 ppm/ $^{\circ}$ C.

5 The solder member **16** may include, *inter alia*, a solder ball such as a controlled collapse chip connection (C4) solder ball. The solder member **16** may include, *inter alia*, a eutectic lead-tin alloy (i.e., about 63% lead and 37% tin, by weight), a high-melt lead-tin alloy, a eutectic-tipped, high-melt alloy, an unleaded solder, etc. As an example, the high-melt lead-tin alloy may have lead and tin in a ratio of 97:3 by weight with a melting temperature of about 330 10 $^{\circ}$ C. The solder member **16** has a CTE between about 21 ppm/ $^{\circ}$ C and about 28 ppm/ $^{\circ}$ C. In particular, a lead-tin alloy having a 97:3 weight concentration ratio has a CTE of about 28 ppm/ $^{\circ}$ C.

15 An underfill material **24** exists between the semiconductor substrate **12** and the organic substrate **14**, wherein the underfill material **24** encapsulates the solder member **16**, and wherein the underfill material **24** has an elastic modulus of at least about 1 gigapascal (GPa). The underfill material **24** serves to reduce thermal stresses on the solder member **16**, wherein such thermal stresses may occur during thermal cycling operations. Any underfill material known to one of ordinary skill in the art may be used for the underfill material **24**. Examples of known underfill materials include, *inter alia*, Dexter CNB840-38 and Namics U8437-2.

20 The electronic structure **10** may be fabricated as follows. The semiconductor substrate **12** is formed, or otherwise provided, with the pad **20** thereon. The organic substrate **14** is formed, or

otherwise provided, with the pad 22 thereon. A high-melt lead-tin solder is deposited and shaped on the pad 20 of the semiconductor substrate 12 to form a solder ball. A eutectic lead-tin solder paste is deposited on the pad 22 of the organic substrate 14. The high-melt solder on the pad 20 is placed in contact with the eutectic solder paste on the pad 22. The solder paste is reflowed at a 5 temperature below the melting temperature of the high-melt lead-tin solder, and then cooled, to form the solder member 16 that mechanically and electrically couples the semiconductor substrate 12 to the organic substrate 14. The underfill material 24 may be subsequently placed between the semiconductor substrate 12 and the organic substrate 14 such that the underfill material 24 encapsulates the solder member 16.

Notwithstanding the role of the underfill material 24 in mitigating thermal stresses on the solder member 16, such reduced thermal stresses may nonetheless cause cracking of the solder member 16 at the interface between the solder member 16 and the pad 20. The interface between the solder member 16 and the pad 20 is more prone to thermal stress damage than is the interface between the solder member 16 and the pad 22, because the local mismatch in CTE between the 15 solder member 16 and the semiconductor substrate 12, that is coupled to the pad 20, is greater than the mismatch between the solder member 16 and the organic substrate 14 which is coupled to the pad 22. The thermal stress damage adversely impacts the fatigue life of the interface between the solder member 16 and the pad 20.

The present invention discloses two inventive techniques for extending the fatigue life of 20 the interface between the solder member 16 and the pad 20. With the first inventive technique, a ratio S1/S2 exceeds 1, wherein S1 is a surface area of the surface 32 of the pad 20 of the

semiconductor substrate 12 that is wetted by the solder, and S2 is a surface area of the surface 34 of the pad 22 of the organic substrate 14. With the second inventive technique, a distance in a direction 8 from a centerline 26 of the solder member 16 to a closest lateral edge 13 of the semiconductor substrate 12 exceeds about 0.25 mm. The centerline 26 is defined as passing 5 through a centroid 28 of the solder member 16 and being oriented in a direction 9 that is perpendicular to the surface 32.

By increasing S1 relative to S2, the first inventive technique of having S1/S2 exceed 1 reduces the thermal stress and consequent thermal strain on the solder member 16 at the pad 20 as compared with the thermal stress and consequent thermal strain on the solder member 16 at 10 the pad 22. The first inventive technique offsets a portion of the higher thermal stress on the solder member 16 at the pad 20, wherein said higher thermal stress is due to the relatively higher CTE differential between the solder member 16 and the semiconductor substrate 12, as compared with the CTE differential between the solder member 16 and the organic substrate 14.

FIG. 2 is a table of thermal cycling fatigue test data for the solder member 16 of FIG. 1, 15 which demonstrates that increasing S1/S2 increases the fatigue life of an interface between the solder member 16 and the pad 20 of FIG. 1. In the tests underlying FIG. 2, the electronic structure 10 was thermally cycled from 100°C to 0°C, and back to 100 °C, in each cycle. The semiconductor substrate 12 is a silicon semiconductor chip, the organic substrate 14 is an organic chip carrier comprising a glass epoxy core with organic buildup layers, and the solder member 16 20 is a C4 solder ball comprising a lead-tin alloy having weight concentrations of about 97% lead and about 3% tin. An underfill 24 material of Namics U8437-2 material having an elastic

modulus of 7 GPa was used.

The column titles appearing in the first row of the FIG. 2 are as follows. The “Row” column denotes row numbers. The “Sample Size” column denotes the number of same electronic structure 10 samples used in each batch tested. The “Chip Size” denotes the chip 5 dimensions along surface 18 of the chip 12. The pad 22 has a diameter as denoted in the “Organic Substrate Pad Diameter, D2” column. The pad 20 has a diameter as denoted in the “Chip Pad Diameter, D1” column. The “D1/D2” column denotes the ratio of D1 to D2. The “S1/S2” column denotes S1/S2 such that $S1/S2 = (D1/D2)^2$. The “Solder Ball Height” column denotes the height H in the direction 9 shown in FIG. 1. The “Distance (D_{EDGE}) From Solder 10 Ball Centerline To Chip Edge” column denotes the distance D_{EDGE} in the direction 8 shown in FIG. 1. The “No. Of Cycles to 50% Fails” column denotes the number of cycles at which 50% of the samples failed, which was computed by averaging over the Sample Size. The “First Cycle 15 To Fail” column has a tolerance of 500 cycles, since the samples were tested for failure at every 500 cycles, with the exception of row 5 for which the samples were tested for failure at every 100 cycles. A failure of a sample is defined as crack in the solder member 16 or a delamination of the solder member 16 from the pad 20.

As seen in rows 4 and 3 in FIG. 2, as S1/S2 is increased from 0.40 to 0.77, the No. of Cycles to 50% Fails increases from 3250 to 7963, and the First cycle to Fail increases from 600 to 2500. Note that rows 2 and 3 are consistent with rows 3 and 4, since as S1/S2 increases from 20 0.77 to 0.81, the No. of Cycles to 50% Fails increases from 7963 to 8430. Note that in rows 2, 3, and 4, D_{EDGE} has the same value of 100 μm .

5

The preceding results confirm that increasing S1/S2 improves fatigue life, which is the basis for the first inventive technique of the present invention. Finite element modeling has been used to predict the increase in fatigue life over an extended range of the ratio S1/S2. The first inventive technique includes several embodiments with respect to S1/S2. A first embodiment of the first inventive technique is $S1/S2 > 1$. A second embodiment of the first inventive technique is having S1 exceed S2 by a factor of at least about 1.2. A third embodiment of the first inventive technique is having S1 exceed S2 by a factor between about 1.1 and about 1.3. A fourth embodiment of the first inventive technique is having S1 exceed S2 by a factor between about 1.3 and about 2.0.

10

Rows 1 and 3 of FIG. 2 demonstrate the second inventive technique of the present invention. D_{EDGE} equals 230 μm (i.e., .23 mm or 9 mils) and 100 μm (i.e., .10 mm or 4 mils) for rows 1 and 3, respectively. For rows 1 and 3, FIG. 2 shows that the Number of Cycles to 50% Fails increases from 7963 cycles to 13260 cycles as D_{EDGE} is increased from 100 μm to 230 μm (i.e., from .10 mm to .23mm). Thus, at distances D_{EDGE} within hundreds of microns from the nearest chip edge 13 (see FIG. 1), increasing D_{EDGE} results in going to more cycles to reach the 15 50% failure level. Note that in rows 1 and 3, S1/S2 has the same value of 0.77.

15

The beneficial effect of increasing D_{EDGE} within hundreds of microns from the nearest chip edge 13 is also illustrated by FIGS. 3 and 4. FIGS. 3 and 4 are plots of average shear strain and average axial strain, respectively, on the solder member 16 at the interface between the 20 solder member 16 and the pad 20 of the semiconductor substrate 12. The average shear strain in FIG. 3 is in a plane that is defined by directions 8 and 9 in FIG. 1, whereas the average axial

strain in FIG. 4 is parallel to the direction 9. Both the shear strain in FIG. 3 and the axial strain in FIG. 4 are spatially averaged over the portion of the pad surface 32 that interfaces the C4 solder ball 16.

In FIGS. 3 and 4, the semiconductor substrate 12 is a silicon semiconductor chip, the organic substrate 14 is an organic chip carrier comprising a glass epoxy core with organic buildup layers, and the solder member 16 was a C4 solder ball comprising a lead-tin alloy having weight concentrations of about 97% lead and about 3% tin. An underfill 24 material is present with a modulus of from 2 to 11 GPa. The edge 13 of the chip 12 is about 8 mm from the center (not shown) of the chip 12. The surface 18 of the chip 12 has dimensions of 16mm x 16mm. The height H of the C4 solder ball is 0.1 mm.

In the simulations underlying FIGS. 3 and 4, the electronic structure 10 was thermally cycled from 100°C to 0°C, and back to 100 °C, in each cycle. The resulting shear strain in FIG. 3 and axial strain in FIG. 4 are each plotted as a function of D_C , wherein D_C is a distance in the direction 8 from the center of the semiconductor substrate 12 to the centerline 26 of the solder member 16 (see FIG. 1). FIG. 3 shows three shear strain curves 102, 105, and 111, respectively corresponding to elastic modulii of 2 Gpa, 5 Gpa, and 11 Gpa of the underfill 24. Similarly, FIG. 4 shows three axial strain curves 202, 205, and 211, respectively corresponding to elastic modulii of 2 GPa, 5 GPa, and 11 GPa of the underfill 24.

In FIG. 3, the average shear strain falls most sharply when the C4 solder ball centerline 26 is between about 0.25 mm and about 0.40 mm from the edge 13 of the chip 12, depending on which of the three curves 102, 105, and 111 is relevant. The 0.25 mm distance is the change in

D_C between the point P_1 on the curve 111 (where a sharp change in slope occurs) and $D_C = 8$ mm corresponding to the edge 13 of the chip 12. The 0.40 mm distance is the change in D_C between the point P_2 on the curve 105 (where a sharp change in slope occurs) and $D_C = 8$ mm corresponding to the edge 13 of the chip 12.

5 In FIG. 4, the average axial strain falls most sharply when the C4 solder ball centerline 26

is between about 0.30 mm and about 1.0 mm from the edge 13 of the chip 12, depending on which of the three curves 202, 205, and 211 is relevant. The 0.30 mm distance is the change in D_C between the point P_3 on the curve 211 (where a sharp change in slope occurs) and $D_C = 8$ mm corresponding to the edge 13 of the chip 12. The 1.0 mm distance is the change in D_C between the point P_4 on the curve 202 (where a sharp change in slope occurs) and $D_C = 8$ mm corresponding to the edge 13 of the chip 12. Based on the preceding results, the second inventive technique includes several embodiments with respect to D_{EDGE} . With a first embodiment of the second inventive technique, based on the average shear strain curves of FIG. 3, D_{EDGE} is at least about 0.25 mm. With a second embodiment of the second inventive

15. technique, based on the average shear strain curves of FIG. 3, D_{EDGE} is at least about 0.40 mm.

With a third embodiment of the second inventive technique, based on the average axial strain curves of FIG. 4, D_{EDGE} is at least about 0.30 mm. With a third embodiment of the second inventive technique, based on the average axial strain curves of FIG. 4, D_{EDGE} is at least about 1.00 mm.

20 The present invention's effectiveness relates to the fact that the interface between the

solder member 16 and the pad 20 is more prone to thermal stress damage than is the interface

between the solder member 16 and the pad 20, because there is a greater difference in CTE

between the solder member 16 and the pad 20 than between the solder member 16 and the pad

22. Accordingly, a CTE coupling parameter P characterizes the aforementioned differentials in

CTE, wherein P is defined as $(C_{SOLDER} - C_{ORGANIC})/(C_{SOLDER} - C_{SEMI})$, wherein C_{SOLDER} is a CTE of

5 the solder member 16, wherein $C_{ORGANIC}$ is a CTE of the organic substrate 14, and wherein C_{SEMI}

is a CTE of the semiconductor substrate 12. Assuming that $C_{SOLDER} > C_{ORGANIC} > C_{SEMI}$, P must

satisfy $0 < P < 1$. $P=1$ represents a perfectly symmetric distribution of said differential CTE

between the pad 20 and the pad 22, while $P=0$ represents a perfectly asymmetric distribution of

said differential CTE between the pad 20 and the pad 22. For the ranges of CTE stated *supra* for

10 the solder member 16, the organic substrate 14, and the semiconductor substrate 12, P satisfies

.17 < P < .72. Thus, a comprehensive range for P is $.15 < P < .75$ for the range of CTEs

considered herein.

While embodiments of the present invention have been described herein for purposes of illustration, many modifications and changes will become apparent to those skilled in the art.

15 Accordingly, the appended claims are intended to encompass all such modifications and changes

as fall within the true spirit and scope of this invention.
